

ABSTRACT

1 A method and system for enabling users of a network to create, store, and provide
2 access to relationships between document objects stored on the network. The method
3 may include the steps for allowing a user of the network to create a link relationship
4 between a first document object and a second document object; for storing the link
5 relationship in one or more link directories; and for providing all users of the network
6 access to the link relationships stored in the one or more link directories based upon the
7 document object currently accessed by the users. The system may include one or more
8 client devices that access document objects stored on the network and create link
9 relationships between the first document object and the second document object; and one
10 or more servers that store and filter the link relationships created by the client devices and
11 transmit one or more link relationships and link references to the client devices.
